1.0 OVERVIEW OF THE PROJECT

Travelers have encountered many issues when it comes to booking either manually or through existing online platforms, such as slow interfaces, lengthy booking processes, limited availability, high prices, unfriendly user experiences, and complicated payment methods. These issues are further exacerbated by the threat of scams that are becoming more rampant nowadays. In fact, according to the Thales Group, the threat of cybersecurity has become alarming, as the emergence of AI and organized syndicates has made the threat more serious for both the airline industry and traveler safety. (“The rising cyber”, 2024) Because as we transit toward the future world where digital will be an inseparable part of our lives, it makes this matter more important than ever. On 23 March, a cyberattack by a group of an organized syndicate on KLIA rendered the airport's online system inoperable. This has triggered an alarm about the safety of the online system. (Nizam, 2025) It's critical for the development of the airline online booking system to be greater than the current existing system, as the threat is evolving. While providing a seamless experience to both the customer and the company that operates the system. Hence, our objective is to form a system application that will fulfill all the requirements, but at the same time, it will not jeopardize the security. That is when Elvanta Tech discovers that it is inconvenient for the customer to go through all of these problems. Elvanta Tech finds an idea to create the Velaris Flight Ticket Booking System to improve flight ticket booking systems by finding the solution for all the problems faced by customers. This will give customers a better experience and be able to increase the sales.

The online booking platform has various features to arrange schedules and handle the bookings part. For flight ticket booking systems through online platforms, there are airlines and OTAs such as Kayak, Expedia, and Skyscanner. These platforms all offer online flight management, booking, and search services. The service provided, including flight search and selection, will feature real-time availability, as well as options for searching, comparing, filtering, and sorting. For booking and payment, the platform will offer features such as a streamlined booking process, secure payment processing, and support for multiple currencies. In terms of booking management, it will include functionalities for viewing booking details, making modifications,

handling cancellations, and processing refunds. Additional services will also be available, including baggage information, loyalty program integration, and customer support.

Velaris Flight Ticket Booking System is developing an Airline Reservation System (ARS), a software commonly used by airlines to manage and store flight information, passenger data, and booking records. It serves as a centralized database for flight schedules, seat availability, fare details, and passenger profiles. This system helps to improve the process of searching, booking, and purchasing flight tickets online. Nowadays, most of the customers have high expectations towards the flight ticket booking system. This makes the other system very hard to cope with and leads to customer dissatisfaction with that system and reduces the sales. They want a convenient, simple, responsive, user-friendly, and fast response where they can access it 24 hours anywhere. This study aims to create an integrated system and a user-friendly interface that allows customers to easily access any flight information in real-time, manage their own bookings, and be able to complete their payment through online payments. Velaris will have administrators that have tools to manage all the flight schedules and are able to operate while monitoring all the bookings efficiently. Velaris' goal is to have an efficient operation, reduce all the administrative overhead, and enhance the overall travel experience for all the customers by implementing this system for Velaris.

2.0 PROBLEM STATEMENT

The problem statement for this project is to address and solve the limitations present in an existing flight ticket booking system, such as searching for flights, selecting available flights, and paying for the reservation. All of this discovery led to the creation of an improved airline reservation system through the Velaris Flight Ticket Booking System. The Velaris Flight Ticket Booking System aims to overcome issues such as:

1. Complex user interfaces

Complicated user interfaces will result in a dashboard that loads with all the icons, making it impossible to jump to the next page and select a flight. Customers also faced confusion due to the complex and non-intuitive booking process, which lacked clear guidance and straightforward navigation. Additionally, the customer has a limited number of dates to select from. This caused them to become frustrated, which raised the number of booking errors. Additionally, it will result in a greater reliance on customer service, which raises operating expenses. Customers will not return to this system because of all these issues, as it is not user-friendly, particularly for elderly and busy working adults.

2. Payment failures

The systems experienced payment failures, either declining the payment or loading the page until it timed out. Another problem is that even if the payment fails, the seat stays the same and prevents the customer from making another reservation for a flight ticket. Hence, the customer will lose their trust in their payment towards the system, and the system will lose all the potential sales.

3. Payment and refund issues

When a customer has already made the payment and that particular payment is successful, but the system was loading or the internet was down, it will lead to an unsuccessful booking, which will cause the flight system to refund pages. There are also system timeouts that happen while the payment gateway is processing. Customers may also pay more than the original price in cases where the system incorrectly converts the

currency. All of these problems, however, were not resolved quickly, and they were consistently postponed or said that refunds were either unsuccessful or not possible due to an inefficient system.

4. Security vulnerabilities

Regarding system security, the system might not be up to date with the most recent version, which leads to outdated encryption protocols and a decreased level of trust. This can result in insecure Application Programming Interfaces (APIs) with weak authentication mechanisms, potentially leading to customer data breaches. The government may impose regulatory fines when a company fails to follow the law, especially in cases where customer data is leaked to unauthorized parties. As a result, customers may lose trust in the airline.

5. Search and filtering inefficiencies

When customers have difficulty finding flights using the search function, it indicates that the system has a poor filtering mechanism for flight ticket availability, often providing delayed or inaccurate results. Furthermore, the absence of specific times or dates for flights makes it difficult for customers to find the best ticket options, which may cause them to abandon the platform and choose not to return.

6. Language and localization failures

A flight ticket booking system should support multiple languages to be globally accessible, helping attract and retain customers from around the world. If the system lacks translation features, it can be difficult for customers to select flight times accurately. Additionally, if the system is not accessible 24/7 and does not support time zone handling, international customers may face challenges when trying to book flights at their convenience. As a result, we risk losing potential global customers.

3.0 PROPOSED SOLUTIONS

I. Feasibility Study

- Improving productivity for end users (customers and airport personnel).
- Streamlined workflows tend to greater end-user experience.
- A well-planned flight ticketing system from the front end and back end enables a smooth workflow.
- The flight ticketing system selection procedures naturally lead to a user-friendly interface (front end).
- Real-time monitoring shows the most accurate data directly.
- Continue to maintain a reliable and consistent connection to the flight ticketing system.

II. Element of feasibility

1. Technical Feasibility

- Review the integration capabilities
- Check the current system of the requested company is capable of handling the add-on process later.
- Identify the resource that meets the expectations.

2. Economic Feasibility

- Cost of estimate for the entire project, including system study, employees' studies, and software/hardware.
- Forecast extra revenue within the flight ticketing system
- Cost possible financial risks with the airline due to unexpected expenses.

3. Operational Feasibility

- Evaluate end-user readiness and acceptance for an upgraded flight ticketing system.
- Make backup preparations for the data.
- Assess the impact on daily operations so as to analyze system possibilities.

III. Cost - Benefit Analysis (CBA)

COSTS		Year 0	Year 1	Year 2	Year 3	Year 4
Development Cost (One-time)

Figure 2.0: Cost-Benefit Analysis Velaris Booking Ticketing System

4.0 CURRENT BUSINESS PROCESS/WORKFLOW

SCENARIO 1 :

A family of Japanese—dad, mom, and kids, 5 years old and infant—living in Kasukabe. Dad has been promoted to factory manager and is bringing high profits to the company. Dad wants to spend their holiday in Koh Samui. His wife, Mrs Nohara has to search for information about the flight.

Mrs Nohara is searching for the flight that is friendly to infants and kids. For a long journey flight, consider more legroom and comfort, a night flight to coincide with the baby's sleep schedule, specific service for a bassinet, and assistance with infant care. She is also prefer her to use her local language while using the booking system.

They never been in Thailand, so Mrs Nohara wants to know where they will be land at airport before heading to Koh Samui. Her son is a picky eater, she needs to choose what the meal served on the plane.

As a frugal housewife, Mrs Nohara seeks for the best affordable flight available.

UX shows an additional icon for the user to put in some requests. The system will search for suitable drop-down flight listings that match the user's preferences.

Scenario 1 has includes

Complex user interfaces (problem 1), search and filtering inefficiencies (problem 5), and language and localization failures (problem 6).

WORKFLOW

Figure 4.0 Workflow

5.0 LOGICAL DFD (AS-IS)

This logical data flow diagram (DFD) (AS-IS) is based on the current flight booking ticket system, which is AirAsia. In project 2, we already included this logical DFD (AS-IS), but in P3 we have to improvise it to a new version for the child diagram. The context diagram and diagram 0 remain the same.

6.0 SYSTEM ANALYSIS AND SPECIFICATION

The System Analysis and Specification of the Velaris Flight Ticket Booking System provides a detailed roadmap for how the system should function to overcome the existing limitations in traditional airline booking platforms. It begins with the development of a Logical Data Flow Diagram (To-Be), which includes a context diagram showing system interactions with users and external services, followed by Diagram 0 and child diagrams that break down and detail each process such as login, flight availability checking, booking, and data retrieval. Each process is carefully documented with inputs, outputs, rules, and error-handling conditions to ensure reliable performance. The system defines multiple user roles with assigned permissions, enhancing security and user experience. To safeguard user data, the system incorporates encryption, secure APIs, and multi-factor authentication. It also prioritizes accessibility by supporting multi-language options, time zone synchronization, and international currency handling. Robust error recovery mechanisms are integrated to address issues like payment failures or session timeouts. Furthermore, the system is designed to be scalable, modular, and cloud-ready, ensuring flexibility for future growth and integration with third-party services. This comprehensive specification ensures that Velaris is not only efficient and secure but also adaptable to the evolving needs of global travelers.

6.1 LOGICAL DFD (TO-BE)

The Logical DFD (To-Be) provides a visual representation of how data will flow through the improved Velaris Flight Ticket Booking System. It outlines the future state of the system by breaking down key processes such as login, flight search, booking, and payment into structured diagrams that show interactions between users, system components, and data stores. This helps stakeholders understand how the redesigned system will function more efficiently, securely, and intuitively compared to the current version

Process 6.1, 6.2 and 6.3: Sent notification

Figure 6.7 Child Diagram for sent notification process 6.1, 6.2 and 6.3 of Logical DFD (TO-BE)

6.2 Process Specification

Process 1: Authenticate User

- Description: Validates the login information provided by the customer.
- Input:
 1. Login credentials (from Customer)
 2. User database (D1)
- Output:
 1. Login confirmation or error (to Customer and Process 2)
- Process Logic:
 1. Receive login credentials.
 2. Check if credentials match records in the User database (D1).
 3. If matched, return login confirmation.
 4. If not, return an error message.

Process 2: Availability of flight

- Description: Check the availability of flights based on passenger's preference
- Input:
 1. Passenger search criteria
 2. Customer details
- Output:
 1. Availability of flights

- 2. Seat availability
 - 3. Flight information
- Process logic
 - 1. Start process
 - 2. Retrieve available flights
 - 3. Check seat availability
 - 4. Display flight options

Process 3: Handle Booking Request

- Description: Handles e-booking requests after user identification and availability verification.
- Input:
 - 1. E-booking request (from Customer)
 - 2. Login confirmation (from Process 1)
 - 3. Availability (D3)
- Output:
 - 1. Payment information (to Process 3)
 - 2. Booking and payment details (to Process3)
 - 3. Booking records update (D2)
 - 4. Generate e-ticket request (to Administrator)
- Process Logic:
 - 1. Receive and validate the e-booking request.
 - 2. Check Availability (D3) for the needed tickets.

3. If possible, gather payment details.
4. Keep track of preliminary bookings in Booking Records (D2).
5. Forward booking and payment information to Process 3.

Process 4: Process Payment

- Description: Processes payments made by customers and generates invoice data.
- Input:
 1. Booking and payment details (from Process 2)
 2. Administrator (manual approval or oversight)
- Output:
 1. Invoice details (to Administrator and Process 4)
 2. Transaction summary (to Customer)
 3. Update Payment Records (D4)
- Process Logic:
 1. Receive payment information.
 2. Validate and handle payments.
 3. Save payment information in Payment Records (D4).
 4. Generate and deliver a transaction summary to the customer.
 5. Forward invoice information to Process 4 and Administrator.

Process 5: Generate e-tickets

- Description: E-tickets are generated after payment has been confirmed.

- Input:
 1. Email instruction & invoice details (from Process 3)
- Output:
 1. Ticket records update (D6)
 2. E-ticket details (to Process 5)
 3. Customer invoice details (to Customer)
- Process Logic:
 1. Receive payment confirmation and booking information.
 2. Create an e-ticket with passenger and booking information.
 3. Store in Ticket Records (D6).
 4. Send invoice and e-ticket to the customer.
 5. Send e-tickets to the notification system (Process 5).

Process 6: Send Notification

- Description: Notifies the customer and the administrator by e-ticket.
- Input:
 1. E-ticket details (from Process 4)
 2. Booking request & passenger details (from Customer)
- Output:
 1. Booking confirmation/error (to Customer)
 2. Notification (to Administrator)
- Process Logic:

1. Collect e-tickets and passenger information.
2. Format and send notification to the customer.
3. Notify Administrator about the new booking

7.0 PHYSICAL SYSTEM DESIGN

The physical system design of the Velaris Flight Ticket Booking System is the implementation of a logical data flow diagram. There are diagram 0, child diagram, partitioning, CRUD Matrix, event response table, structure chart and system architecture that will be used for designing the physical system. The physical data flow diagram shows that process involved with going into detail about the physical aspect of the activity. In this system, the process will be separated into two types of process which is performed by human or automatic. The process in diagram 0 and the child diagram process will have more details compared to the logical data flow diagram. The order of the process should be in sequence. In this system, it needs a process for adding, deleting, changing and updating records. There are temporary data stores, the files that have actual names and add control to ensure the process is done properly.

7.1 PHYSICAL DFD (TO-BE) SYSTEM

    Step45 --> Notify[Notify user about  
payment success or  
failure]
    Notify --> End
    
```

The flowchart illustrates the payment processing system with the following components and flow:

- Input:** Payment details (card info, billing address)
- Step 4.1:** Validate Payment Details (Front-End Interface). This step interacts with the **D1 User Database** and the **D5 General System Database**.
- Step 4.2:** Initiate Payment Request (Back-End Server). This step sends the payment request to the **D4 Payment Records** and the **Payment Gateway (External Service)**.
- Step 4.3:** Payment Gateway (External Service). This step sends the payment status (success/failure) from the payment gateway to the **Payment Confirmation (Back-End Service)**.
- Step 4.4:** Payment Confirmation (Back-End Service). This step interacts with the **D5 General System Database** and sends data to **Step 4.5** and **Step 4.6**.
- Step 4.5:** Update Transaction Status (Database). This step sends a notification to the user about payment success or failure.
- Step 4.6:** Generate Receipt (Back-End Service). This step interacts with the **D5 General System Database** and sends the receipt to the **Sent Receipt (Email)** step.
- Step 4.7:** Sent Receipt (Email). This step sends the digital receipt to the customer via email for confirmation.

Table 7.0 Crud Matrix

Event Response Table

The following table is the event response table. This table summarizes the flow of the system in the Velaris Flight Ticket Booking System platform. It was created and developed based on the research from project 1 and 2 where we conducted questionnaires and interviews. We also do some research by reading through journals. It is developed by the user experience which is the process of logging in, choosing language, searching for flights, booking, making payment, cancelling and requesting for refund. It also shows the admin experience in generating invoice and booking cancellation. This table consists of event, source, trigger, activity, response and destination that show how the Velaris Flight Ticket Booking System platform operates from customer and admin view when they use this booking system. It is also linked to the physical system data flow diagram that is drawn in diagram 0 and child diagram.

Event	Source	Trigger	Activity	Response	Destination
Customer logs on	Customer	Customer click login button	Login	Redirect to dashboard	Customer
Customer choose language	Customer	Customer click the language button	Check availability of language	Display the list of language	Customer
Customer search for flights	Customer	Customer type the search button	Check availability of flights	Display all the list of available flights with dates and time	Customer
Customer book a flight	Customer	Customer selects a flight	Book the ticket	Show booking confirmation and invoice generate	Customer

Customer requests booking information	Customer or Admin	Clicks the button of view booking	Retrieve information	Display booking and trip data	Customer or Admin
Admin views the invoice	Administrator	Admin clicks the button of view invoice	Generate invoice	Display or download invoice	Administrator
Customer makes payment	Customer	Customer submits payment details	Payment processing	Store the payment and show confirmation	Customer
Ticket generation is confirm	System	Payment is verified	E-Ticket generate	Email the E-Ticket to customer	Customer (Through Email)
Customer cancel booking	Customer	Customer click cancel booking	Cancellation of booking	Store the refund information, update booking status	Customer or Admin

9.0 SUMMARY OF THE PROPOSED SYSTEM

The Velaris Airlines Ticket Booking System is a completed, web-based application that makes it easier to automate the whole process of booking airline tickets for both customers and airline staff members. The system's goal is focused on improving the effectiveness, accuracy, and convenience of handling aircraft reservations, payments, and passenger records. The site provides real-time airline schedules, seat availability, fare options, and expected journey times, allowing users to make informed decisions. Overall, the Velaris Airlines Ticket Booking System aims to reduce human error, remove manual paperwork, shorten processing times, and provide a seamless booking experience for modern travels, all while providing the airline with sophisticated management and decision-making tools.
